

Dashboard Feedback - English Version

2026年8月9日 星期日 23:03

Is this a data issue, or is the scale on the horizontal axis too small? It is difficult to see the ranking differences among the three stores.

Possible solutions:

1. Adjust the scale of the horizontal axis.
2. Would it be possible to directly display the current Net Sales ranking?

like this:

Since the chart next to it already shows Sales by Product Category, would it be better to change this one to Sales by Product Name? This would make it easier to identify which specific products are more likely to be slow-moving or best-selling.

Note: I think this section can be moved to the abnormal orders page instead of being removed. I previously came across a case where a customer cancelled an order after a gift card payment failed and decided not to continue with the purchase. Therefore, this table could be used as supporting information when investigating the causes of abnormal or cancelled orders.

For the Vendors and abnormal orders sections, I think these charts are sufficient. I cannot think of any additional visualizations that would provide meaningful value at this point.

Summary: I think the current version should be sufficient for Checkpoint 5. Overall, there are still three components that need to be completed:

1. Employee attendance dashboard
2. Slow-moving product analysis
3. Operating expenses pie chart

Once these three components are completed, I think the dashboard will be ready for the Final Submission. Thank you for all the work on this!

Assuming the store closes at 10:00 PM, the previous update time would correspond to the inventory data recorded at the end of the previous business day.

The calculation method would be as follows:

Use the inventory levels recorded at the beginning and end of each business day over the past two weeks as the basic data points. Then identify products whose inventory level either did not change during the day or changed by no more than 10 units.

The output could include the product_name, category_id, and the difference between the opening and closing inventory levels.

For example, suppose a product has the following daily sales over the past two weeks:

5, 6, 4, 5, 7, 3, 5,
1, 9, 5, 2, 8, 5, 5

Then the sales value displayed on the dashboard would be 5.

To access this page, the user would need to enter an employee ID and password. Only store managers would have permission to view this dashboard.

After clicking here, the user would be taken to the store detail page, which could be designed as shown:

Question: Should we display the role_description when the user hovers the mouse over the employee information?

If possible, this section could use a horizontal carousel, allowing users to scroll left and right to view attendance information for different employees.

A bar chart may not be the best choice here. It could be changed to large KPI numbers to make the information more intuitive.

Since completed orders generally do not require further attention, the dashboard should focus on unresolved and cancelled orders, as these are the ones that still require action. A similar design can be seen in the SHEIN interface.

I am not completely sure what this chart is intended to show. What business problem is it designed to address?

These three tables could be combined into one section.
